*BLOOD LEAD - A FUNCTION OF VEHICULAR EMISSIONS AND SMOKING.*

Foreword

This is Part II of a report on an investigation, done in May 1983, of blood lead and air lead levels in two towns Holmestrand (moderately exposed to lead via vehicular emissions) and Sørumsand (control low exposure area). Part I summarizes the principle findings of the study.

Part II of this report contains the results of a series of analyses that were considered peripheral to the main body of the report. Therefore Part II is merely a collection of Appendices.

## Table of contents

|              |   |
|--------------|---|
| Appendix I   | Means and standard deviations of parameters that were not included in further analysis because of insignificance. |
| Appendix II  | Comparison of findings using hematocrit corrected and uncorrected blood lead.                                     |
| Appendix III | Comparison of air lead exposure estimates corrected and uncorrected for respiratory ventilation.                  |
| Appendix IV  | Comparison of logarithmic treated data to non-logarithmic treated data.   |
| Appendix V   | Results of the analysis of hematocrit.  |
| Appendix VI  | Results of the analysis of corrected zinc protoporphyrin  |

### APPENDIX I

Means, standard deviations and samples size (N) of parameters that were not included in further analysis because of insignificance.

Values expressed as  $\mu\text{g/dl}$ .

$$\text{Pb-B } (\mu\text{g/dl}) = \text{Pb-B } (\mu\text{moles/l}) \times 20.72$$

Since Pb-B is log-normally distributed, it is incorrect to use means and standard deviations.

The more correct form is to use the median with the standard deviation of the natural logarithm. However, it is doubtful how many individuals would find this understandable. Therefore, it was decided to present the data as means and standard deviations. None of these findings were used in the final statistical analyses. For further discussion of this problem and comparison of findings, see Part I - pages 36 and 39.

Table I-1: Blood lead ( $\mu\text{g}/\text{dl}$ ) in men and women in the two towns by age group.

|             |                | Age Group (yrs)     |             |            |             |             |            |             |            |             |            |

<sup>1</sup> Blood lead is hematocrit adjusted.

**APPENDIX II**

Comparison of findings using standardized and unstandardized blood lead concentrations. Blood lead levels are standardized by:

$$CPbB = \frac{PbB \times 45.0}{Ht}$$

- CPbB = standardized blood lead concentrations
- PbB = unstandardized blood lead concentrations
- Ht = Hematocrit

Table II-1: Output of multiple regression analysis using DOPP (Jakobsen, 1982) for children (upper) and adults (lower) where blood lead uncorrected for hematocrit (not logarithmic) is the dependent variable, and the independent variables include smoking (passive smoking with children), exposure to air lead, social class and sex. The highly significant F values for passive smoking and air lead in children and sex and air lead in adults is evident.

### *APPENDIX III*

- 1) Multiple regressions using air pollution exposure estimates not corrected for respiratory ventilation and respiratory ventilation corrected exposure estimates.
- 2) Standard statistics of both estimates. See discussion on page 7.

Table III-1: Multiple regression analysis using DDPP (Jakobsen, 1982) where blood lead (non-logarithmic) is the dependent variable and the independent variables include:

- 1) for children (upper) social class, passive smoking and air lead (uncorrected for respiratory ventilation).
- 2) for adults (lower) social class, air lead (uncorrected for respiratory ventilation) sex, and smoking.

F-values are very similar to those on the following page.

**APPENDIX IV**

Comparison of logarithmic treated data to non logarithmic treated data. Frequency distributions.

Table IV-1: Frequency distributions of air lead exposure estimates (API) for the entire populations of both Holmestrand and Sørumsand.

The upper figure represents the data without logarithmic transformations. The lower figure represents the data with natural logarithmic transformations.

Additional statistics accompany each set.

Table V-5: Multiple regression of:

Hematocrit versus logarithm of blood lead, smoking, sex and social class in adults living in Holmestrand and Sørumsand.

Results: 1) There is a significant correlation of sex with hematocrit with females having the lower value.

2) There is no significant correlation of any of the other variables.

Further similar multiple regressions on each subject - males and females - led to no significant results.

### APPENDIX VI

Results of the analyses of standardized zinc protoporphyrin.  
Zinc protoporphyrin was standardized by:

$$\text{CZPP} = \frac{\text{ZPP} \times 45.0}{\text{Ht}}$$

CZPP = standardized zinc protoporphyrin

ZPP = unstandardized zinc protoporphyrin

Ht = hematocrit

See page 7 for a commentary on the use of means and standard deviations.

Table VI-1: Frequency distributions of zinc protoporphyrin, standardized for hematocrit with relevant statistics:

a) both towns; b) Sørumsand; c) Holmestrand.

Table VI-6: Multiple regression of:

the logarithm of standardized zinc protoporphyrin versus logarithm of blood lead, passive smoking, and hematocrit in children living in Holmestrand and Sørumsand.

Results: 1) There is a significant negative correlation of hematocrit with zinc protoporphyrin.

2) No other variables have a significant correlation.

Table VI-7: Multiple regression of:

the logarithm of standardized zinc protoporphyrin versus logarithm of blood lead, smoking, sex and hematocrit in adults living in Holmestrand and Sørumsand.

Results: 1) Hematocrit had a significant negative correlation with zinc protoporphyrin.

2) Sex had a significant correlation with zinc protoporphyrin with males having the higher value.
