SUMMARY

OXIDATE is a joint project of European OECD countries to collect and distribute regional data on ozone, nitrogen dioxide and PAN. These data can be of interest to those involved in assessing effects of oxidants, modelling the temporal and spatial distribution, and to others who are interested in photochemical oxidants in general. The OXIDATE project was started in 1985 under the OECD programme "Control of Major Air Pollutants (MAP)".

Each country has nominated a contact person and an institution responsible of collecting data. The data have been sent in a specified format to the project secretariat. The data are then redistributed on magnetic tape to all the participating countries. A summary report is made for each year giving a brief overview of the project organisation and the concentration levels.

In the third year of the project, data have been received from 36 measurement stations in these 11 countries: Austria, Belgium, Denmark, Federal Republic of Germany, Finland, France, Netherlands, Norway, Sweden, Switzerland and United Kingdom. Ozone was reported from 33 stations, nitrogen dioxide from 12 and PAN from three stations. There has been no centrally organised intercalibration or other data control activity. The measurement methods used were chemiluminescence or UV absorbtion for ozone, chemiluminescence for nitrogen dioxide and gas chromatography with electron capture detection for PAN.

As previous years, the highest ozone concentrations were measured in the eastern part of Austria (Illmitz), with the highest hourly concentration reaching $335 \mu\text{g}/\text{m}^3$. This maximum concentration is in comparison with the highest concentration in 1986 ($348 \mu\text{g}/\text{m}^3$) but lower than the maximum in 1985 ($446 \mu\text{g}/\text{m}^3$). In 1987, however, ozone concentrations were only available at Illmitz during a few weeks, making comparisons of extremes difficult.

The ozone data have indicated a gradient in ozone concentrations with lower levels in the north-western part and higher levels towards the central and south-eastern parts of Europe. This gradient was similar

to that of 1985 and 1986, but the gradient was weaker and also more difficult to determine for 1987.

The days with high ozone concentrations were distributed according to the air trajectory sectors. The distribution of sector directions for which high ozone concentrations were measured was in many cases significantly different from the distribution over the total half-year period.

There is a need to include more countries and measurement stations in the project in order to improve the understanding of the oxidant phenomenon. Data from East Europe and the Mediterranean area are of great interest in future European joint measurement programmes.

OXIDANT DATA COLLECTION IN OECD-EUROPE 1985-87 (OXIDATE)

Report on ozone, nitrogen dioxide and peroxyacetyl nitrate,
October 1986 - March 1987,
April - September 1987
and
October-December 1987

1 INTRODUCTION

Episodes of high concentrations of ozone occur over north-western Europe every summer (Cox et al., 1975, Guicherit and van Dop, 1977, Schjoldager et al, 1981, Grennfelt and Schjoldager, 1984). During these episodes the ozone concentrations can reach values above ambient air quality standards over large regions.

The large scale oxidant phenomenon in Europe was first observed from measurements in southern England 1971 (Atkins et al., 1972). During an episode in June/July 1971 ozone concentrations in excess of $200 \mu\text{g}/\text{m}^3$ were observed in connection with high concentrations of particulate sulphate. The observations were made in a high pressure situation with light easterly winds. They suggested that the pollutants originated in continental Europe. The first assessment of ozone data from several stations in Europe was made by Guicherit and van Dop (1977). They examined four ozone episodes between 1971 and 1975 using data from the Federal Republic of Germany, France, Italy, Netherlands, Sweden and United Kingdom. A study of ozone episodes in north-western Europe was done for the years 1976-79 by Schjoldager et al. (1981). Data from 24 monitoring stations in 8 countries were collected and evaluated. The relations between photochemical oxidant episodes, large scale weather and air trajectories were analysed.

For data after 1980 Lübkert et al. (1984) have published a report describing episodes with data from several countries. The report was a result of an OECD workshop in Schauinsland, Federal Republic of Germany, in October 1984. Three episodes were described, one from 1980

and two from 1982. The objective was to provide data for model validations. Besides these reports with data from several countries, a number of publications have appeared presenting and evaluating data from smaller regions.

Because of the regional scale of the photochemical oxidant phenomenon, a successful control of the oxidant problem will only be reached by joint efforts in several countries. At present, several research institutions are involved in modelling work on large scale oxidant formation and transport. Of particular interest is the Dutch-German PHOXA project (Photochemical Oxidant and Acid Deposition Model Application), and the work carried out in Norway within the framework of the European Monitoring and Evaluation Programme (EMEP) (Stern and Builtjes, 1986; Hov et al., 1985).

International bodies, e.g., ECE, EC and OECD, are concerned with abatement strategies. The OECD is currently finishing a programme on "Control of Major Air Pollutants (MAP)" on an international scale. The programme is concerned with long-range transport of air pollutants and large-scale formation of secondary atmospheric pollutants, particularly photochemical oxidants and their precursors. The programme involves several activities; emission inventories, assessment of ambient photochemical concentrations and their effects, implementation and refinement of models for formation and transport of oxidants, and compilation of data on techniques and costs for the control of emissions of nitrogen oxides and volatile organic compounds.

For the assessment of effects and for the model refinement and validation, a comprehensive data base on ambient air concentrations is necessary. Since no permanent or long term (i.e. several years) network have so far existed in Europe for the monitoring of photochemical oxidants, Norway and Sweden offered, during the OECD workshop in 1984, to collect data on ozone, NO₂ and PAN from the European OECD countries, and redistribute the data to the participating countries. The project was presented for the Air Management Policy Group (AMPG) at OECD in March 1985 and received general support. It was agreed to include the OXIDATE project in the OECD MAP programme.

The project is being carried out by the Swedish Environmental Research Institute (IVL) and the Norwegian Institute for Air Research (NILU). In 1985 and 1986, the project has been financed by the Swedish Environmental Protection Board (SNV) and the Norwegian State Pollution Control Authority (SFT). In 1987-89, economic support is given by the Nordic Council of Ministers (NMR).

The first project report, covering the period from April through September 1985, was issued in April 1987 (Grennfelt et al., 1987). The second report, covering the period from October 1985 through September 1986, was finished in May 1988 (Grennfelt et al., 1988).

2 ORGANISATION

Each country nominates an institution responsible for collecting national data and submitting them to the project secretariat. The list of contact persons and institutions is given in Table 1.

Table 1: List of contact persons and institutions, OXIDATE project, 1987.

These 11 countries have submitted data for the periods described in this report: Austria, Belgium, Denmark, Federal Republic of Germany, France, Finland, Netherlands, Norway, Sweden, Switzerland and United Kingdom.

3 MONITORING STATIONS

The total number of monitoring stations was 36. The stations are given in Tables 2 and 3, and on the map in Figure 1. 33 stations have reported ozone, 12 have reported nitrogen dioxide, and three stations have reported PAN data.

The monitoring stations in the project have been selected by the countries. All countries report that they have used either chemiluminescence or UV absorption for ozone monitoring, chemiluminescence for NO_2 , and gas chromatography with electron capture detection for PAN.

There have been substantial improvements in both monitoring and calibration techniques for ozone during the last 5-7 years. Most of the ozone data are probably of good quality.

With regard to NO_2 commercially available chemiluminescence instruments have a detection limit in the lower ppb level. PAN instruments need a quite careful inspection and maintenance. This may explain that only three stations have reported PAN.

In the project, no general intercalibration has been performed, nor has there been a general evaluation of the representativity of the stations for the purpose of the project, i.e., to study the regional extent of photochemical oxidants.

4 SUMMARY OF RESULTS

4.1 EXTREME CONCENTRATIONS AND EXCEEDING OF CONCENTRATION LIMITS

Tables of the dates and the number of days and hours with hourly concentrations above certain limits are given for ozone, nitrogen dioxide and PAN in Appendix A-C.

Winter

During the winter periods the highest hourly ozone concentration was $330 \mu\text{g}/\text{m}^3$ (Payerne, Switzerland, 5 October 1986), and the highest daily ozone concentration was $185 \mu\text{g}/\text{m}^3$ (Illmitz, Austria, 6 October 1987).

The highest hourly NO_2 concentration was $691 \mu\text{g}/\text{m}^3$, and the highest daily NO_2 concentration was $456 \mu\text{g}/\text{m}^3$, measured at Harwell (United Kingdom) 8 March 1987.

The highest hourly PAN concentration in the winter periods was $45 \mu\text{g}/\text{m}^3$, measured at Delft (Netherlands) 1 October 1986. The highest daily PAN concentration was $25 \mu\text{g}/\text{m}^3$, measured at Delft (Netherlands) 13 March 1987.

Summer

For the summer half-year table 4 gives the number of hours and days with hourly ozone concentrations exceeding the concentration limits of 120, 150, 200, 240 and $280 \mu\text{g}/\text{m}^3$. Two stations, Svanvik (Norway) and Ammarnäs (Sweden), had no hourly concentrations exceeding $120 \mu\text{g}/\text{m}^3$. Two stations had hourly concentrations above $240 \mu\text{g}/\text{m}^3$. These were Illmitz (Austria) and Payerne (Switzerland).

During the summer half-year, the highest hourly ozone concentration was $335 \mu\text{g}/\text{m}^3$, and the highest daily concentration was $209 \mu\text{g}/\text{m}^3$, measured at Illmitz (Austria) on 31 August 1987 and 28 August 1987, respectively.

The highest hourly NO₂ concentration was 258 µg/m³ (Payerne, Switzerland, 16 September 1987), and the highest daily concentration was 65 µg/m³, measured at Harwell (United Kingdom) on 24 April 1987.

The highest hourly PAN concentration was 33 µg/m³ (Delft, Netherlands, 1 September 1987), and the highest daily concentration was 13 µg/m³, measured on 21 August 1987 at Delft (Netherlands).

Table 4: Number of hours (h) and days (d) with hourly ozone concentrations exceeding 120, 150, 200, 240 and 280 $\mu\text{g}/\text{m}^3$, and maximum hourly and daily ozone concentration ($\mu\text{g}/\text{m}^3$), April-September 1987.

4.2 MONTHLY MEAN CONCENTRATIONS

The monthly mean ozone concentrations are given in Tables 5a and 5b for the winter half-year and the summer half-year, respectively. The monthly mean concentrations at Brotjacklriegel and Schauinsland (Federal Republic of Germany) were relatively high, with some of the monthly mean values equal to or exceeding 100 µg/m³.

Table 5a: Monthly mean ozone concentrations (µg/m³), October-December 1986.

Number in parenthesis: 10-20 daily values, no numbers: less than 10 daily values.

4.3 CUMULATIVE FREQUENCY DISTRIBUTIONS

The cumulative frequency distributions for ozone and nitrogen dioxide are given in Appendix D for the summer half-year April-September 1987. Many stations show a near log-normal distribution in the higher range of the concentrations indicated by near straight lines in the graphs.

The 90, 95 and 98 percentiles of the summer half-year ozone concentrations are given in Figures 2-4 for the different stations. The highest percentile concentrations were experienced at Brotjacklriegel and Schauinsland (Federal Republic of Germany).

Some "percentile isopleths" are indicated on the maps. These are extremely uncertain, partly because of the limited number of stations. As in the previous report, it has been difficult to determine the eastern and southern ends of the isopleths. Also, some nearby pairs of stations, like Schöneben/Brotjacklriegel and Schauinsland/Tänikon make it difficult to determine the isopleths.

The concentration pattern indicates a northeast to southwest ozone concentration gradient in Europe. This gradient seems, however, to be weaker in 1987 than in the two previous years. In 1987 there was slightly higher ozone concentrations in Norway than in Denmark and Sweden, and the concentrations in Switzerland were generally lower than in 1986.

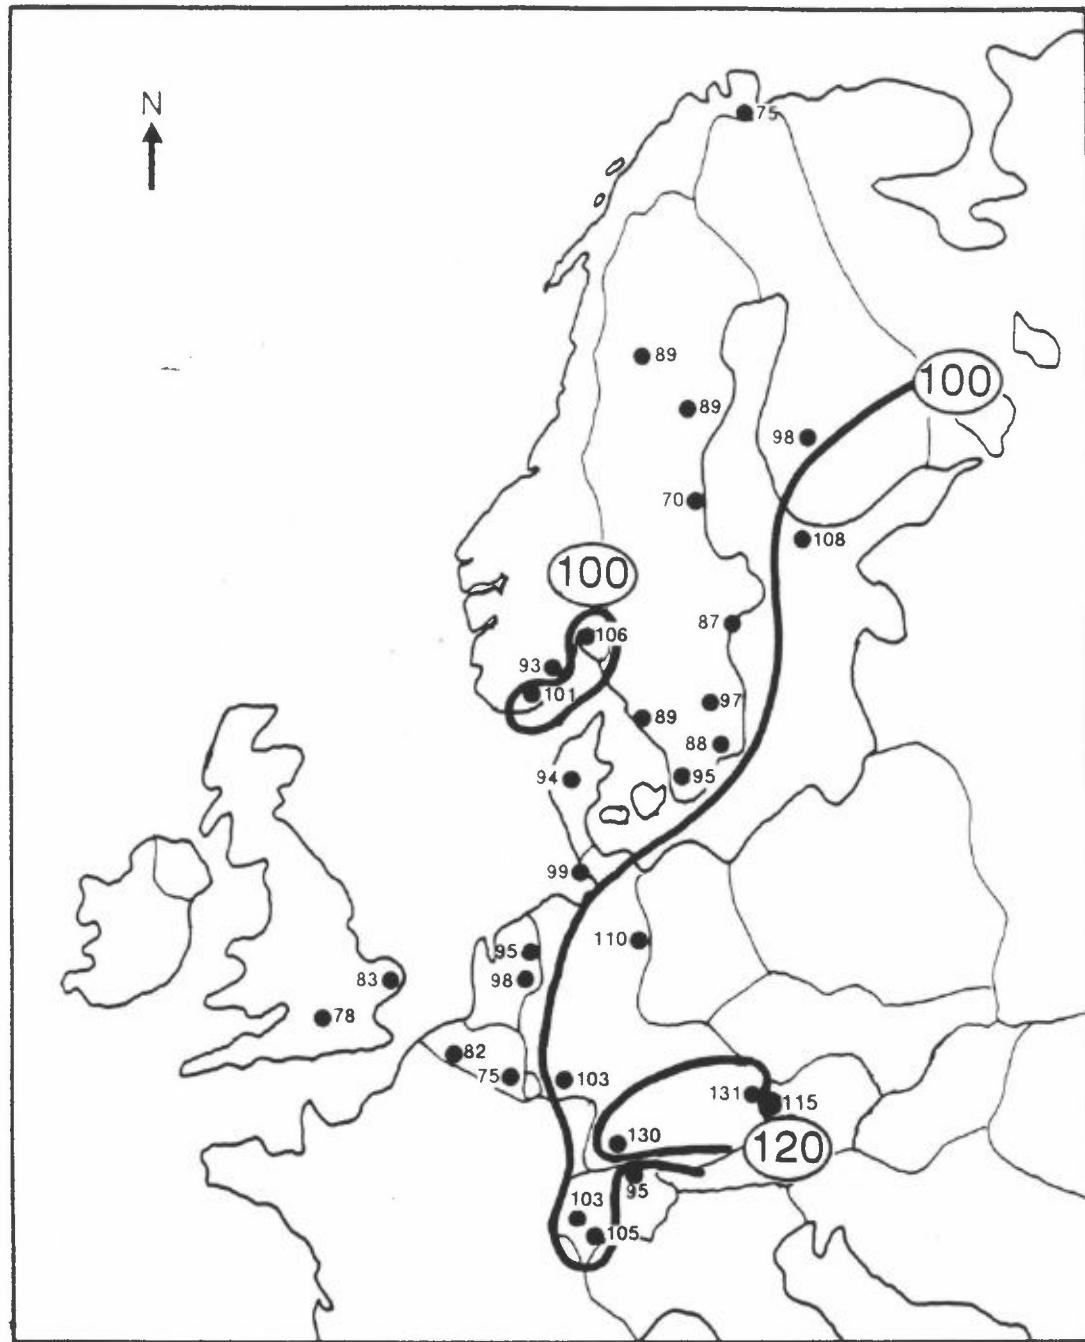

Figure 2: 90 percentile of ozone concentrations ($\mu\text{g}/\text{m}^3$), April - September 1987.

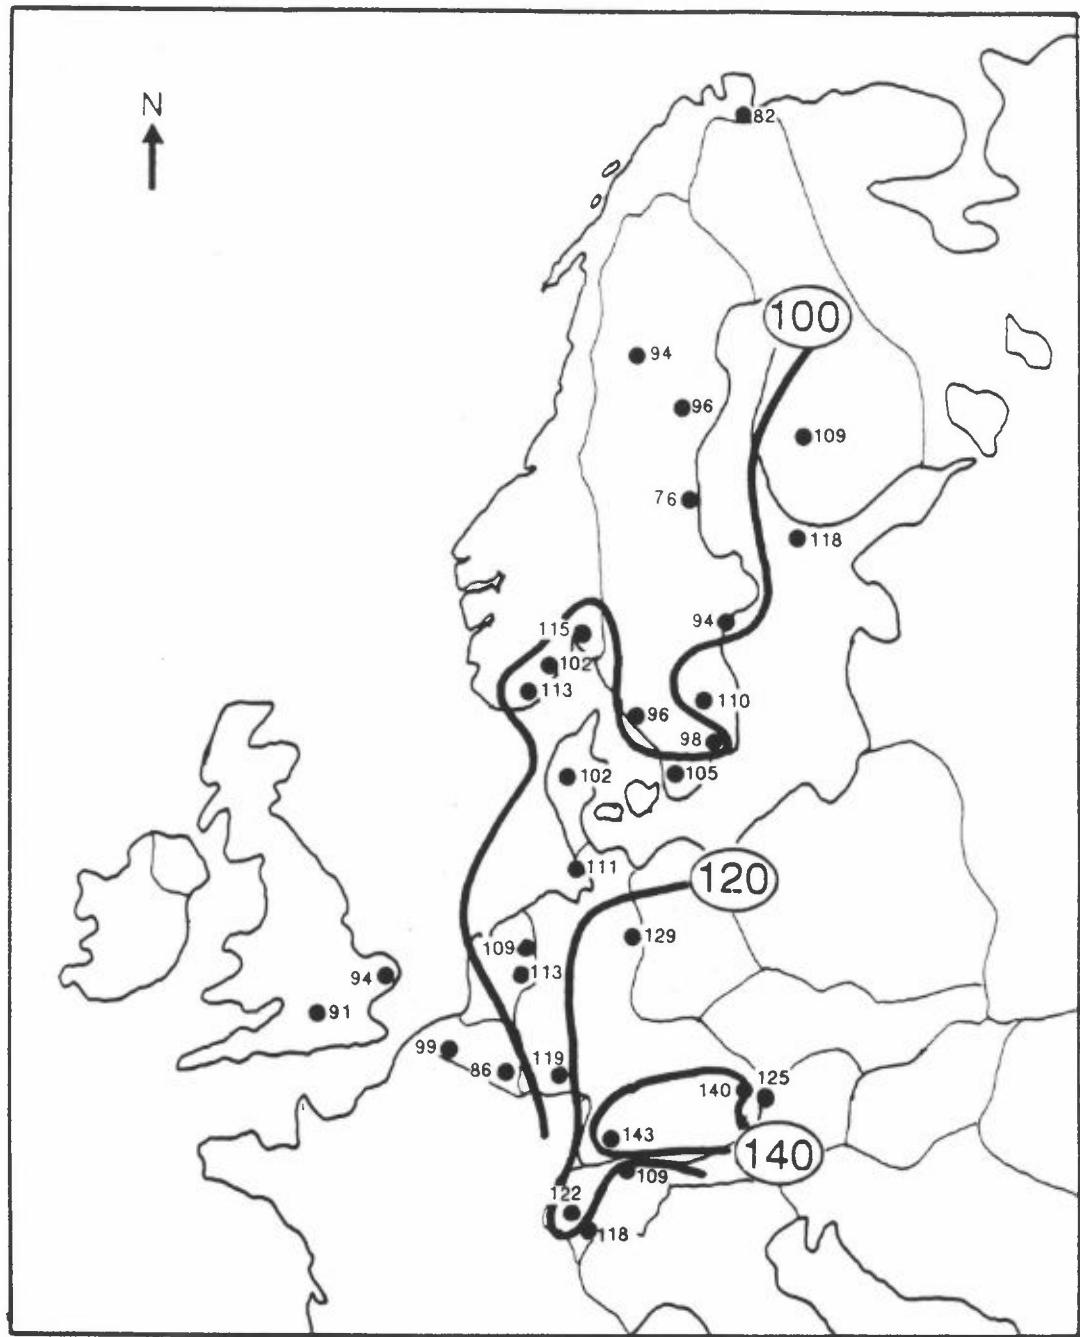

Figure 3: 95 percentile of ozone concentrations ($\mu\text{g}/\text{m}^3$), April - September 1987.

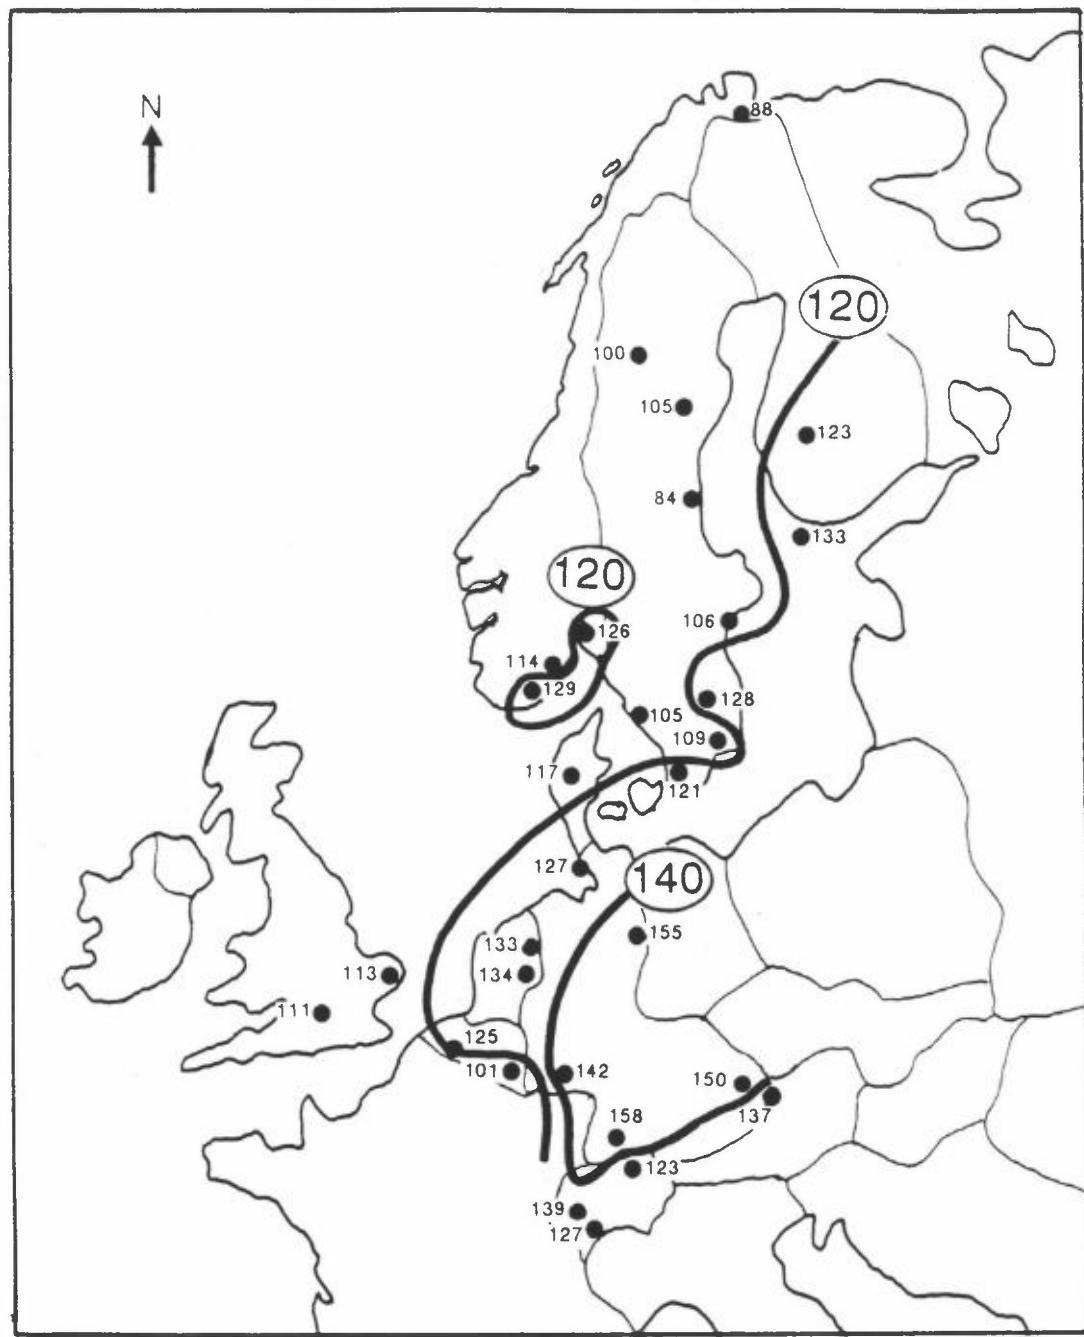

Figure 4: 98 percentile of ozone concentrations ($\mu\text{g}/\text{m}^3$), April - September 1987.

4.4 MEAN DIURNAL CONCENTRATION VARIATIONS

The mean diurnal concentration distributions of ozone and nitrogen dioxide and PAN for the winter half-year are given in Appendix E.

For the summer half-year the mean diurnal concentration distributions of ozone, nitrogen dioxide and PAN are given in Figures 5-6. For ozone, most stations exhibited the well-documented "unimodal" distribution with lowest concentrations during the night and highest concentrations during the afternoon hours. The highest mean concentrations were recorded at Schauinsland and Brotjacklriegel.

Also in agreement with the findings of the previous years, there were smaller concentration variations for coastal stations like Westerland (Federal Republic of Germany) and Utö (Finland), and hilltop stations like Schauinsland and Brotjacklriegel (Federal Republic of Germany) than for most other stations.

The diurnal NO₂ concentration variations showed the "bimodal" distribution for some of the stations, particularly St. Denijs (Belgium) and the three Swiss stations. Eibergen (Netherlands) had a different distribution with higher concentrations during nighttime than daytime hours. The two Finnish stations and Schöneben (Austria) had very small diurnal variations.

The diurnal PAN concentration variations at Creteil (France) and Delft (Netherlands) were similar to most of the ozone concentration distributions, while Donon (France) had small diurnal variations.

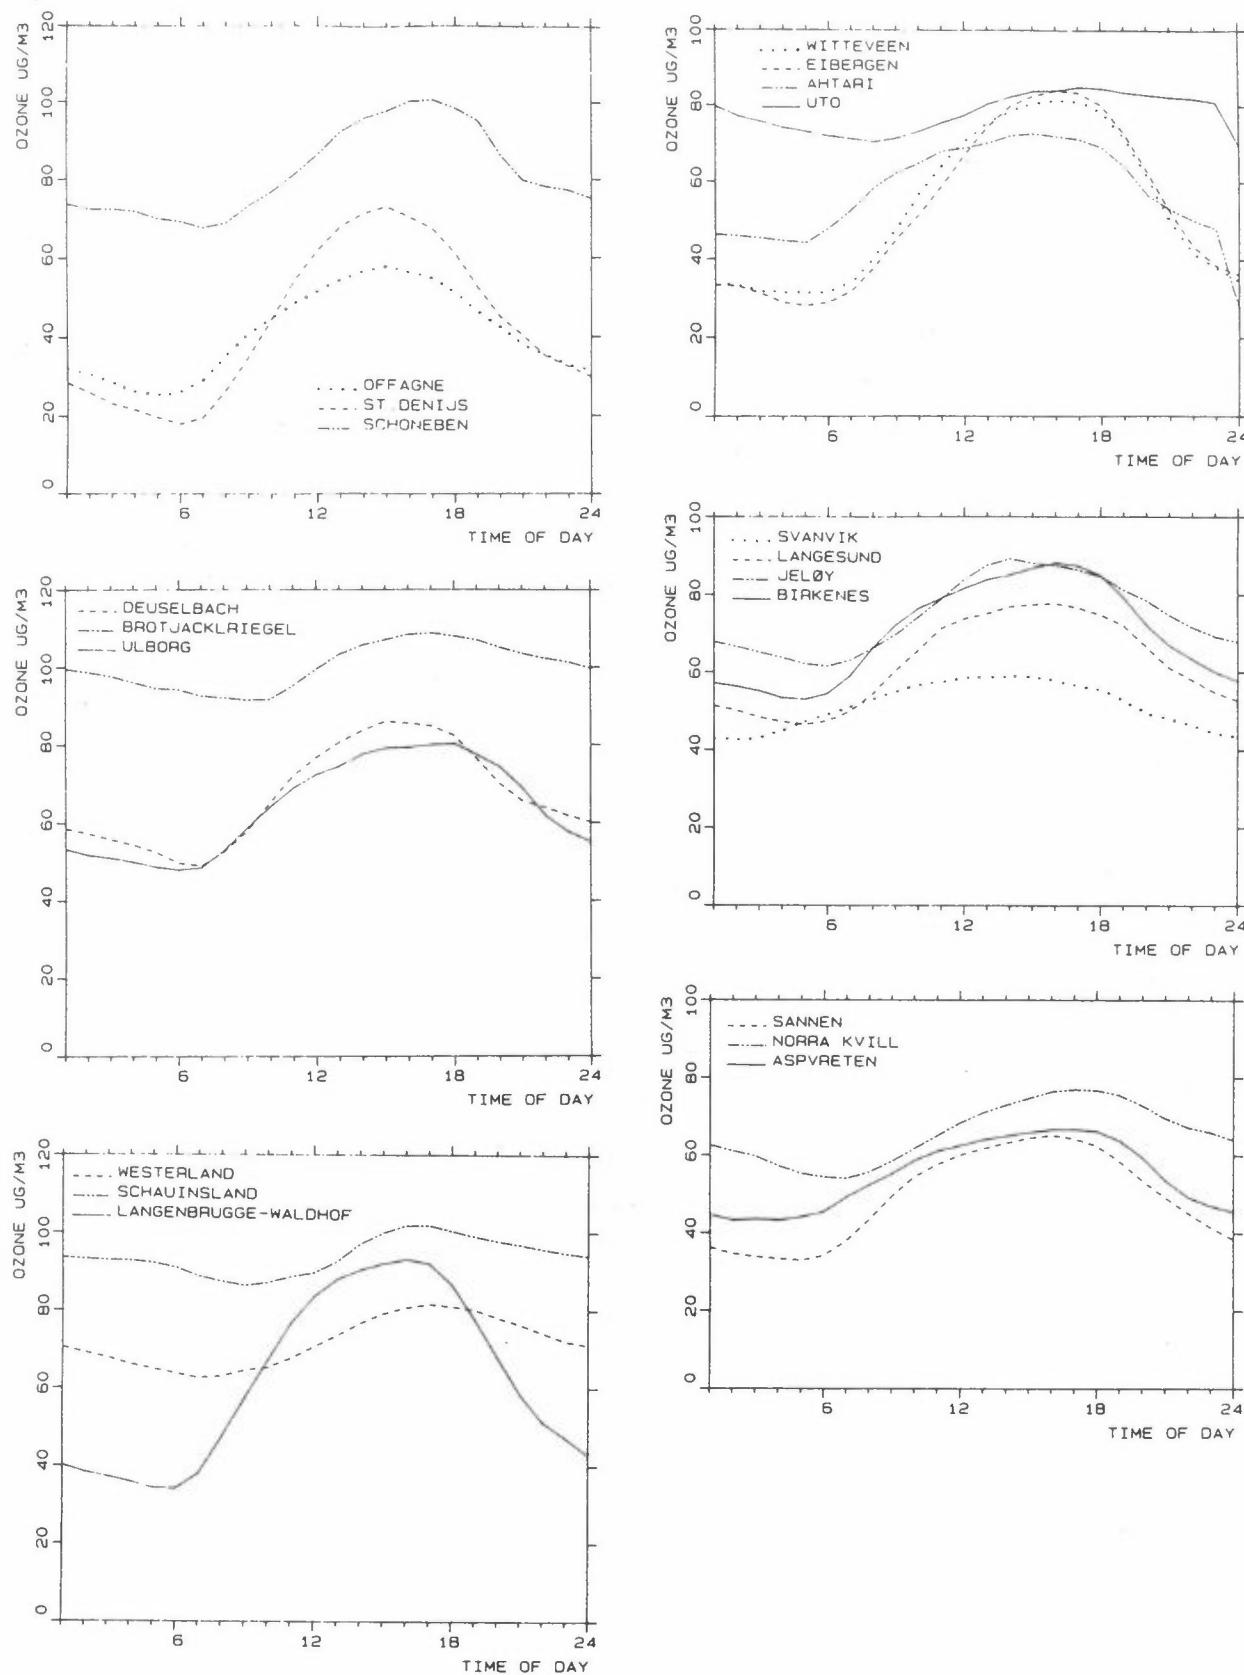

Figure 5: Mean diurnal concentration distributions for ozone, April-September 1987.

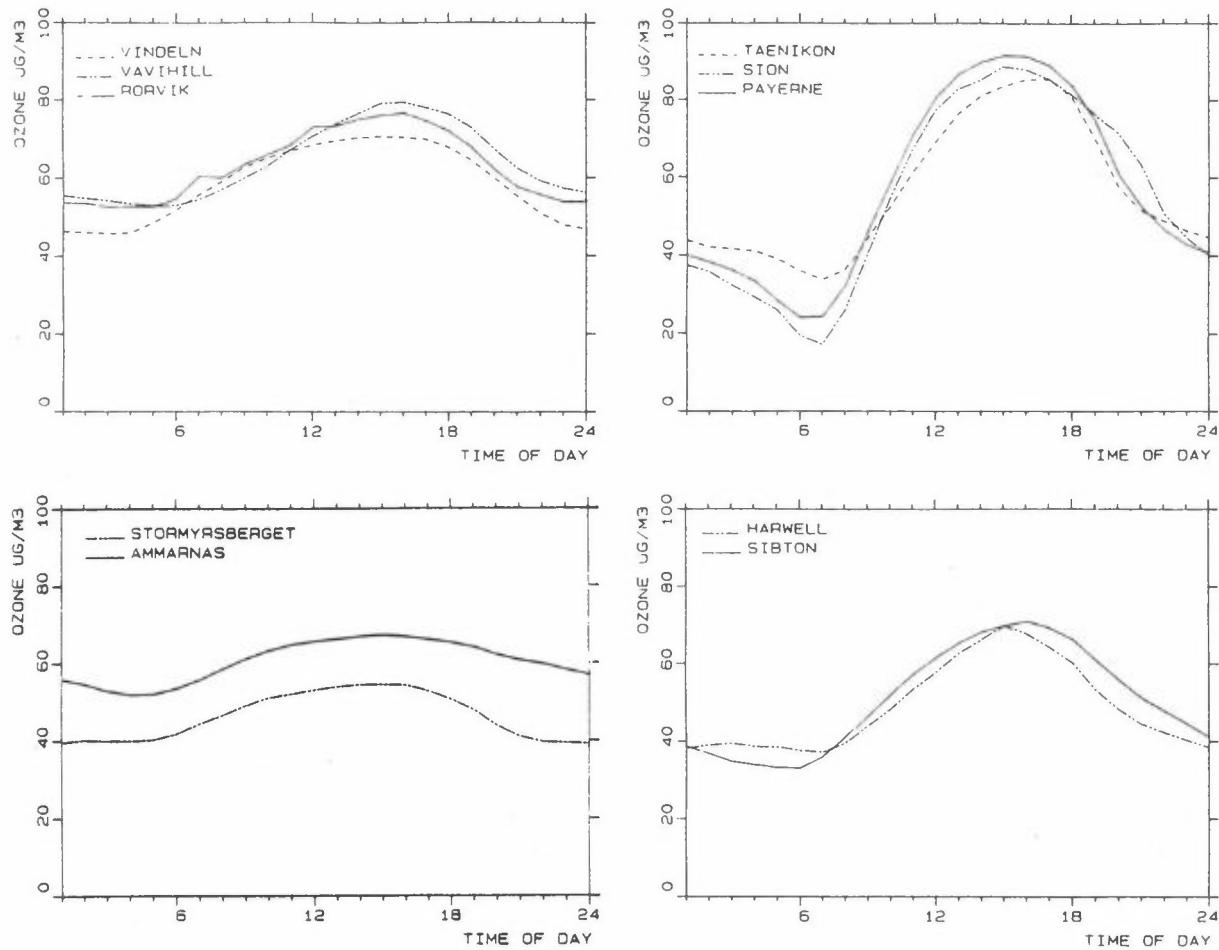

Figure 5 cont.

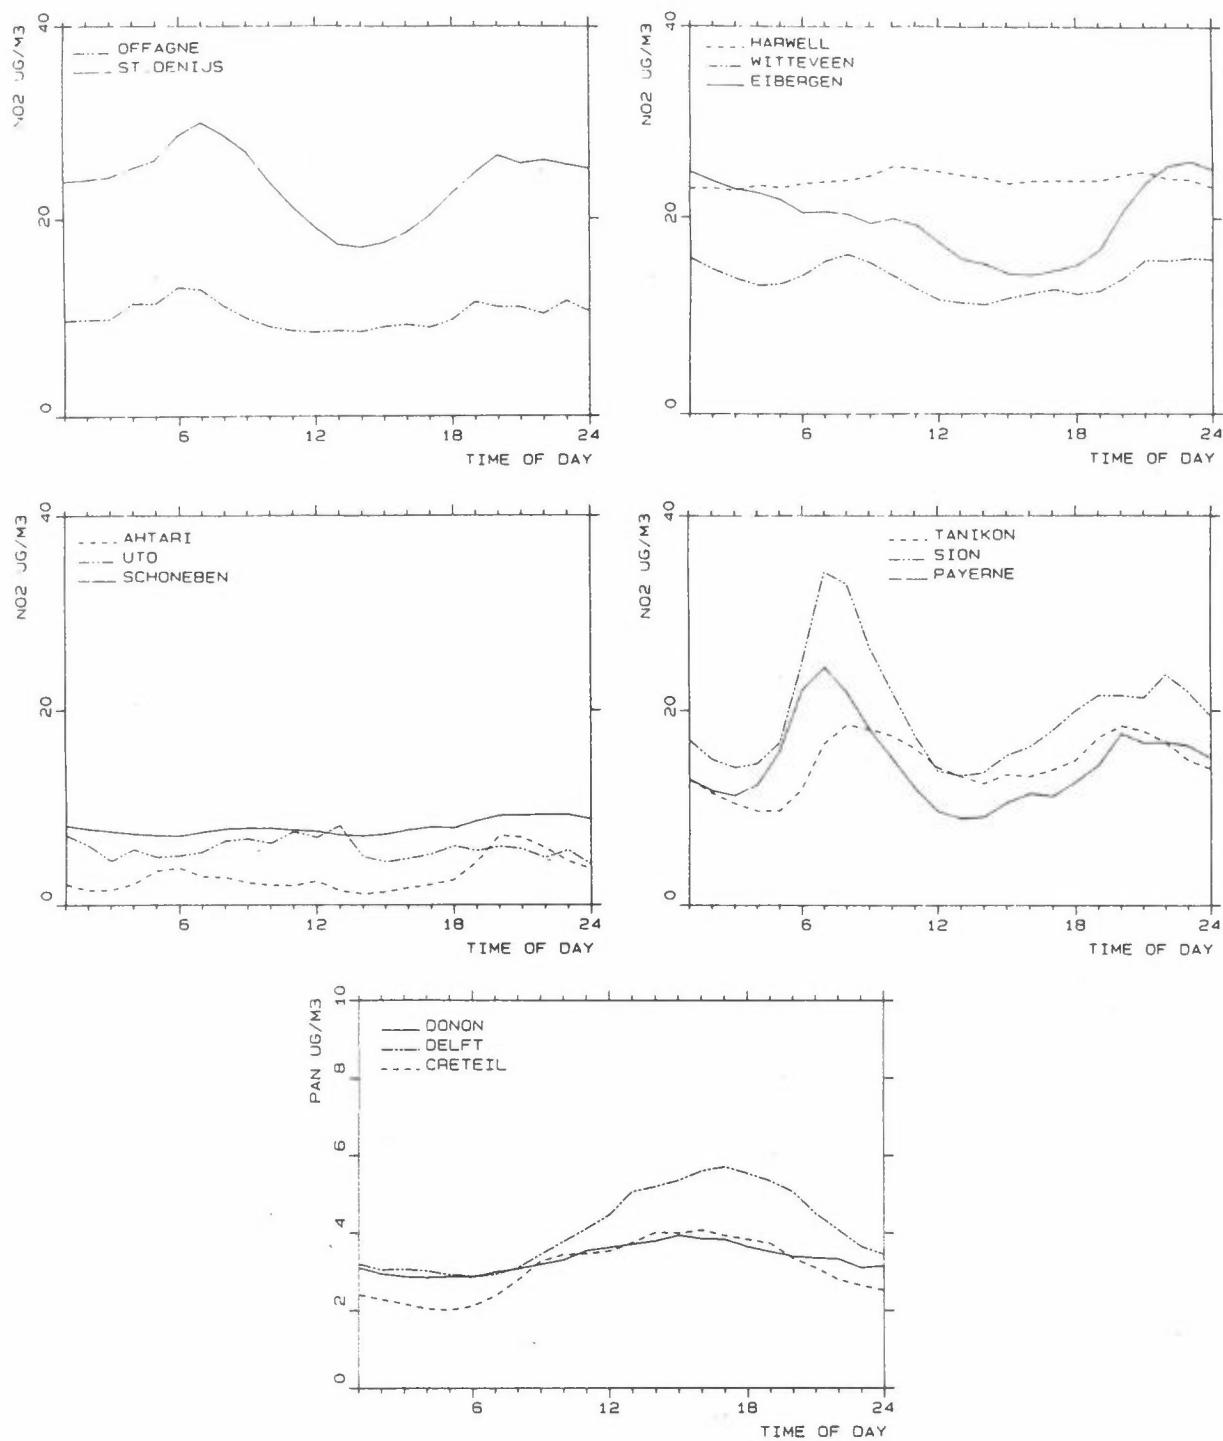

Figure 6: Mean diurnal concentration distributions for nitrogen dioxide and PAN, April-September 1987.

4.5 TRAJECTORY SECTOR DISTRIBUTIONS

The days of the summer half-year period were distributed according to the trajectory sectors. For a certain receptor point, one day is allocated to a 45° sector if the positions of the 96-h back trajectories at the 1000-hPa level arriving on that day are within the sector at least 50% of the time. Only trajectory positions between 150 km and 1500 km from the receptor point are considered. If this criterion is not satisfied for any of the eight 45° sectors, the day is called "undetermined".

The results are given in Appendix F for April-September 1987. "Trajectory roses" are made both for all the days in the half-year period, and for the days on which the maximum 1-h concentration exceeded given limits. The distributions are given as per cent (%) of the number of days meeting the given conditions. For ozone, the concentration limit is $120 \mu\text{g}/\text{m}^3$, $150 \mu\text{g}/\text{m}^3$ and $240 \mu\text{g}/\text{m}^3$ if there were a sufficient number of days.

For NO_2 the concentration limits of $40 \mu\text{g}/\text{m}^3$ and $80 \mu\text{g}/\text{m}^3$ were used. For PAN the concentration limit was $10 \mu\text{g}/\text{m}^3$.

It should be noted, that trajectory sector calculations are associated with many uncertainties, and great caution should be used when trying to indicate emission source areas. This is especially the case for high pressure situations often associated with high oxidant concentrations. Many of these days will have "underdetermined" trajectory sectors.

The distributions for two stations are shown in Figure 9. For Schauinsland the half-year distribution of all trajectories show a dominant transport from the southwest-northwest. The distributions with the limits of $120 \mu\text{g}/\text{m}^3$ and $150 \mu\text{g}/\text{m}^3$ were similar to the total distribution, with increased influence of transport from west for the limit of $150 \mu\text{g}/\text{m}^3$.

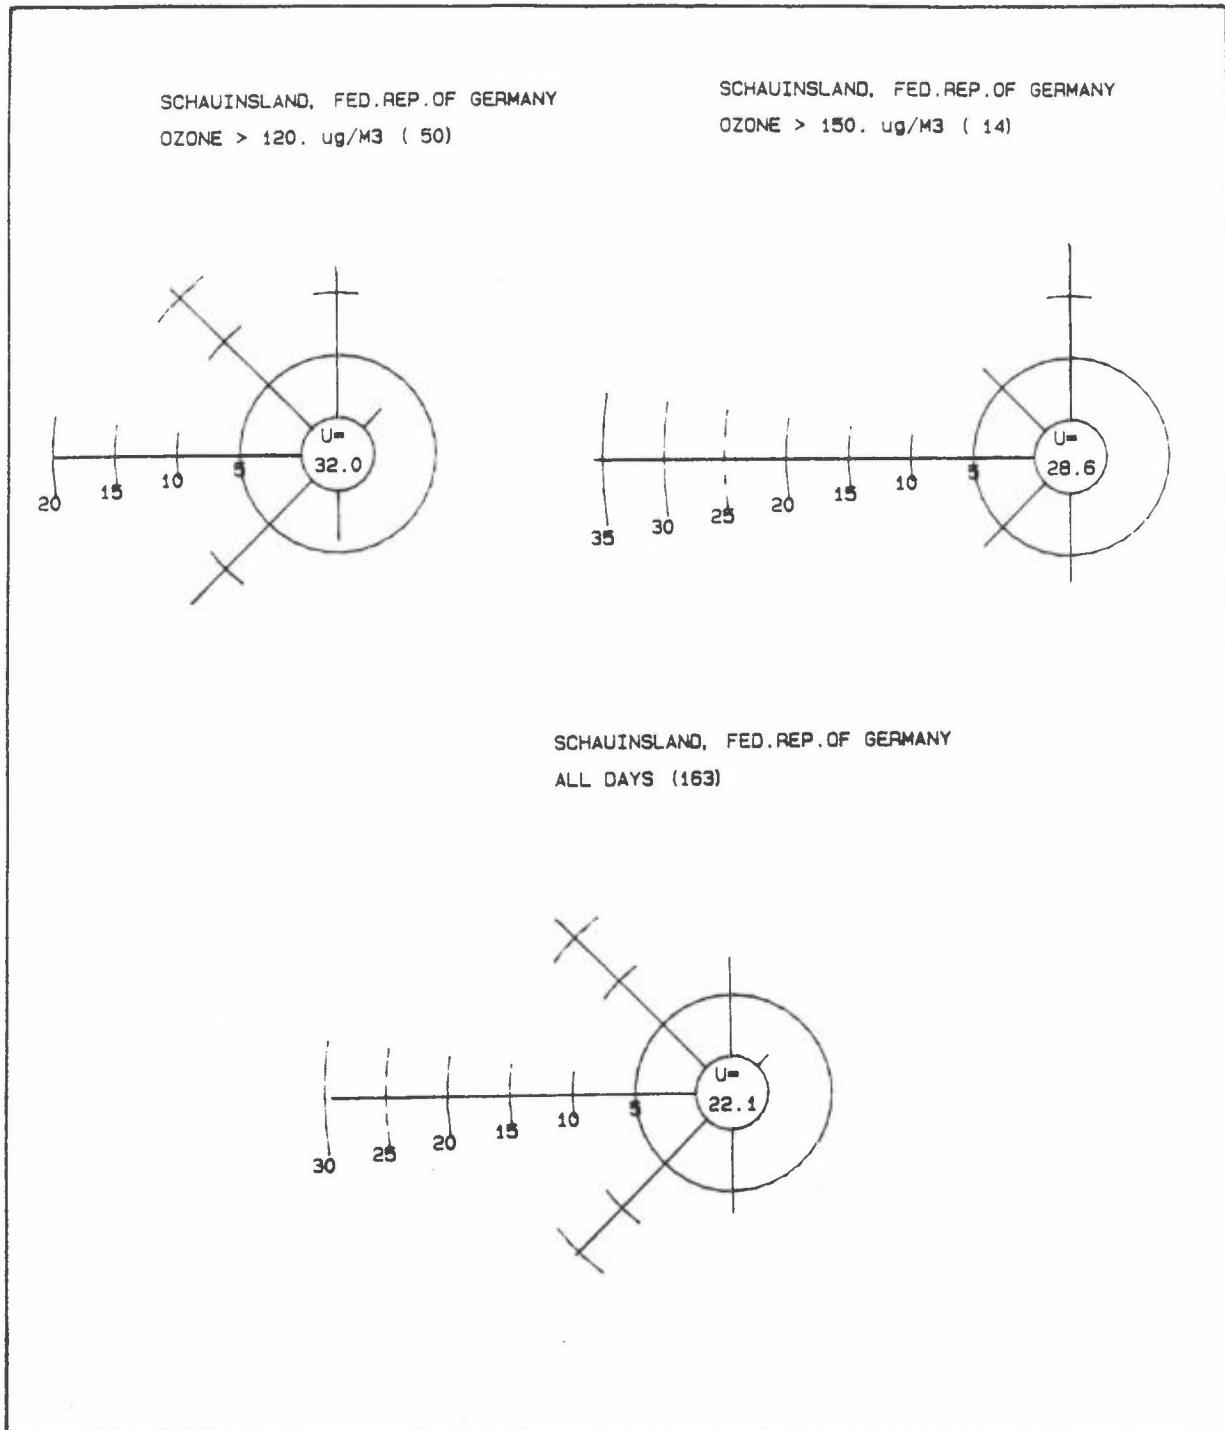

Figure 9: Back trajectory sector distributions (%) for Schauinsland (Federal Republic of Germany) and Payerne (Switzerland), April-September 1987.

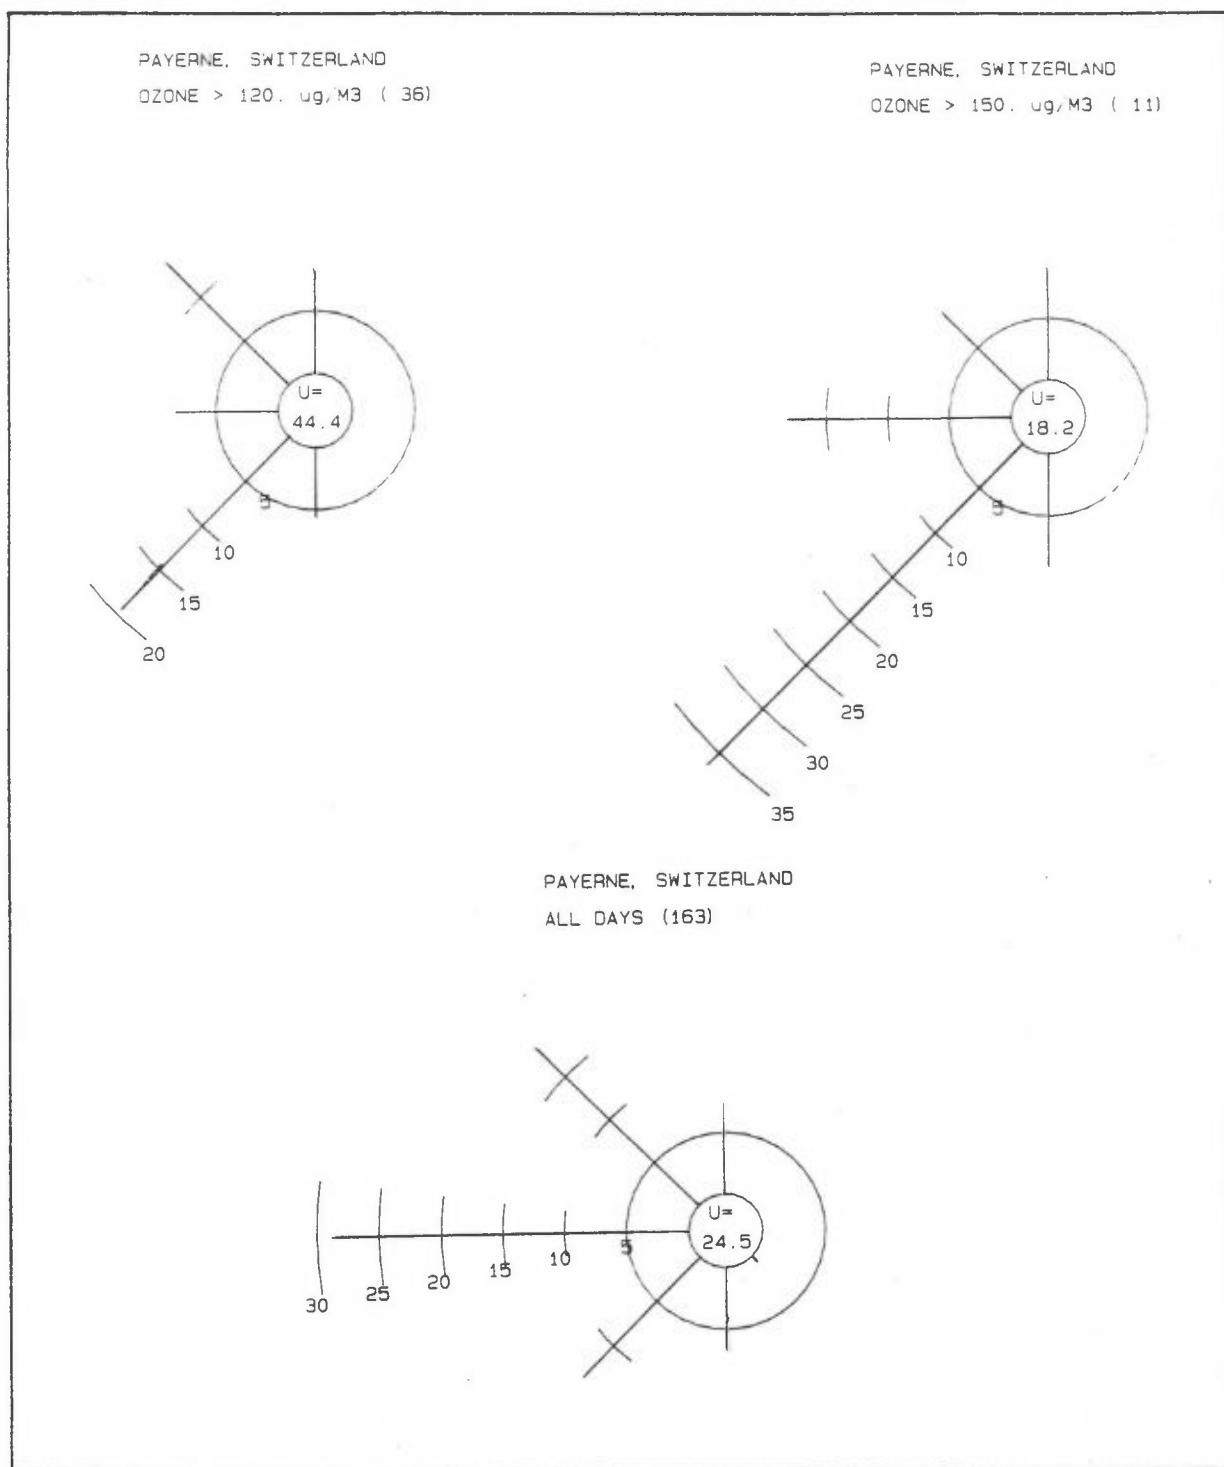

Figure 9 cont.

For Payerne the total distribution was similar to that of Schauinsland, with main directions from the west, northwest and southwest. The days exceeding $120 \mu\text{g}/\text{m}^3$ and $150 \mu\text{g}/\text{m}^3$ had both main directions from the southwest, particularly for the case of $150 \mu\text{g}/\text{m}^3$.

4.6 OZONE EPISODES

In the previous OXIDATE reports, the ozone data from 1985 and 1986 were examined for episodes by using the criterion of an "episode day" as a day when four or more stations recorded a maximum 1-h ozone concentration above $160 \mu\text{g}/\text{m}^3$. In 1985 and 1986, a total of 14 and 20 episode days were found distributed in six and ten episodes, respectively. By using the same criterion for the summer half-year of 1987, 6 episode days were found, distributed in three episodes, 29-30 April, 6-7 July and 21-22 August.

In Table 7 the episode days are presented, back trajectories at the 1000 hPa level are given in Figure 10, and in Figure 11 and Figure 12 weather maps are given (Weather Log, 1987). The maximum hourly ozone concentrations each day are presented in Table 8.

Table 7: Ozone episodes, April-September 1987.

Time period	No. of days	Number of stations with 1-h ozone conc.		Maximum 1-h ozone conc. $\mu\text{g}/\text{m}^3$
		$>160 \mu\text{g}/\text{m}^3$	$>200 \mu\text{g}/\text{m}^3$	
29-30 April	2	8	1	204 Langenbrügge-Waldhof
6-7 July	2	13	4	222 Eibergen
21-22 August	2	8	3	222 Westerland

4.6.1 22-30 April 1987

Although no "episode days" were recorded before 29 April, high concentrations were recorded all the time from 22 to 30 April and the whole period is therefore included in the evaluation of the episode. A high pressure area moved slowly over northern Europe, its centre passing from northern Germany first to the southeast, later to the northwest and north and later again to the east and south. The air masses were first generally coming from the west. Later in the period the directions of the trajectories were variable showing the clockwise circulation around the slowly moving high pressure centre.

Ozone concentrations above $160 \mu\text{g}/\text{m}^3$ were measured in Austria (Schöneben), Federal Republic of Germany (Langenbrügge-Waldhof, Schauinsland and Westerland), Finland (Ahtari), Netherlands (Eibergen), Norway (Birkenes), Sweden (Norra Kvill and Vavihill), Switzerland (Payerne) and United Kingdom (Harwell). The episode thus covered most countries in Europe. The highest concentrations were measured at Langenbrügge-Waldhof ($204 \mu\text{g}/\text{m}^3$).

4.6.2 1-16 July 1987

As for the previous episode elevated ozone concentrations were recorded all the time from 1 July to 16 July and the whole time was included in the evaluation of the episode. A high pressure area over southern England and western France moved slowly to the east, the centre passing over Denmark and North Poland on 5 and 6 July, respectively. A new high pressure area moved over southern England on 8-9 July and then southeast towards France and northern Italy. Towards the end of the period a low pressure area moved from Iceland to the British Isles.

Air trajectories were not available for 1-11 July, but the air trajectories may have been short indicating circulation around the slowly moving high pressure areas. On 12 and 14 July the trajectories came

mainly from the north and west, and on 16 July they were again variable.

Ozone concentrations above $160 \mu\text{g}/\text{m}^3$ were measured in Austria (Schöneben), Belgium (St. Denijs), Denmark (Ulborg), Federal Republic of Germany (Brotjacklriegel, Deuselbach and Schauinsland), Netherlands (Eibergen and Witteveen), Norway (Jeløya), Sweden (Norra Kvill and Vavihill), Switzerland (Payerne) and United Kingdom (Harwell and Sibton). As for the previous episode, this episode covered most of the participating countries, with the highest concentrations measured at Eibergen ($222 \mu\text{g}/\text{m}^3$ on 7 July).

4.6.3 19-24 August 1987

A high pressure area over southern England and France moved towards southern Scandinavia and the western part of the Soviet Union. A low pressure area passed over Great Britain on 22 August and moved east.

The general transport direction of the air masses was from the west, particularly in the first part of the period.

The ozone concentrations were variable, with concentrations exceeding $160 \mu\text{g}/\text{m}^3$ in Denmark (Ulborg), Federal Republic of Germany (Deuselbach, Langenbrügge-Waldhof and Schauinsland), Netherlands (Witteveen) and Switzerland (Payerne and Tänikon). The highest concentrations were measured at Westerland ($222 \mu\text{g}/\text{m}^3$).

5 CONCLUSION

Hourly data on photochemical oxidants from October 1986 to December 1987 are presented from 36 regional stations in Europe. These 11 countries are represented: Austria, Belgium, Denmark, Federal Republic of Germany, Finland, France, Netherlands, Norway, Sweden, Switzerland and United Kingdom.

33 stations have reported ozone, 12 have reported nitrogen dioxide and three stations have reported PAN.

The individual countries have selected the monitoring stations, and they have also been responsible for the quality assurance of the data. No centralised intercalibration or other data quality control has been carried out.

During the summer half-year (April-September 1987), the highest ozone concentrations were $335 \mu\text{g}/\text{m}^3$ (hourly mean) and $209 \mu\text{g}/\text{m}^3$ (daily mean), both measured at Illmitz, Austria. The highest concentrations of nitrogen dioxide were $258 \mu\text{g}/\text{m}^3$, hourly mean (Payerne, Switzerland), and $65 \mu\text{g}/\text{m}^3$, daily mean (Harwell, United Kingdom). The highest concentrations of PAN were $33 \mu\text{g}/\text{m}^3$, hourly mean, and $13 \mu\text{g}/\text{m}^3$, daily mean both monitored at Delft, Netherlands. A complete set of data have been submitted on magnetic tape to all the participating countries.

The magnitude and extension of the episodes with high ozone concentrations are not clear from the data.

The highest ozone concentrations in 1987 were recorded in the southern part of the Federal Republic of Germany. The concentrations in Scandinavia, United Kingdom and the western part of continental Europe were generally lower than in central continental Europe. The gradient through Europe with increasing concentrations from northwest to southeast were generally similar to that of 1985 and 1986, even if the gradient was weaker and also more difficult to determine for 1987.

The air trajectory sector distributions showed that certain trajectory directions in many cases were strongly associated with high ozone concentrations. These directions varied considerably between different regions in Europe and were generally not the same as the main directions for the whole half-year period.

The examination of the data reveals in many cases large variations of concentration levels and patterns between the stations. Further work is needed in order to explain these variations. Local and mesoscale concentration variations of oxidant concentrations are well known and must be taken into account when data from different stations are compared.

There is a definite need to include more countries and measurement stations, in order to improve the understanding of the oxidant phenomenon. Data from East Europe and the Mediterranean area are of great interest in future joint European measurement programmes.

6 ACKNOWLEDGEMENT

We will thank the contact persons from the different countries, given in Table 1, for their interest in the project and the submission of data. We also thank the secretariat of the OECD Environment Directorate for valuable support. Finally we thank Kari Arnesen and Audun Harstad of the NILU staff for the necessary and valuable programming work, and the handling of the data.

REFERAT (maks. 300 anslag, 7 linjer) Rapporten referer timedata fra 36 målesteder i 11 land i Europa. Ozondata foreligger fra 33 steder, NO ₂ -data fra 12 steder og PAN-data fra tre steder. Høyeste timesverdier og døgnverdier er gitt, sammen med kumulative frekvensfordelinger, midlere døgnvariasjon og fordeling på trajektorie-sektorer og en kort drøfting av ozonepisoder.			

TITLE
ABSTRACT (max. 300 characters, 7 lines) The report summarizes hourly data from 36 regional measurement stations in 11 countries. Ozone data is given for 33 stations, nitrogen dioxide data for 12 stations and PAN data for three stations. Extreme values, monthly mean concentrations, frequency distributions, diurnal concentration variations and back trajectory sector distributions are given together with a brief discussion of oxidant episodes.
