Summary

This report is the assimilated record of observed input of atmospheric pollutants to the OSPAR seas in 2003, and of the associated concentrations of pollutants in the ambient air of the OSPAR region. Observations have been conducted under the terms of the CAMP, the Comprehensive Atmospheric Monitoring Programme, which calls for Mandatory Monitoring of a range heavy metals, organic compounds and nutrients in precipitation and air, and encourages participation in a Voluntary Monitoring of additional compounds.

One third of the Parties to OSPAR reported observations of all of the Mandatory components in the CAMP. Despite their Mandatory status γ -HCH (lindane) and mercury were reported least. In general lesser attention was given to pollutants within the Voluntary programme. For example, three quarters of countries did not give attention during 2002 to the monitoring of the atmospheric input of organic substances to their coasts. Parties may wish to consider the issue of implementation of the mandatory and voluntary monitoring programmes. In areas lacking ground truth data, estimates of pollutant load and potential impact must otherwise rest purely on assumptions.

Quality control by some countries remains lower than may be expected. Relatively clear errors are sometimes not being picked up by national data originators. The current contract with the data manager (NILU) does not provide for QA/QC backstopping, and thus the validity of OSPARs monitoring may threatened by lapses in national quality control.

A significant advantage of centralised review of the programme is the potential to note spatial and temporal inconsistencies between locations. After such recent review the example is provided of one Party electing to revise its monitoring programme in the future. Thus, the CAMP and its centralised review can be seen to have led to real benefits in practices. Similar review might be possible in other areas in future. For example, reported concentrations of pollutants are sometimes notably above the levels observed by neighbouring countries at neighbouring sites. Similarly, metal and organic concentrations reported can be below the detection limits, and in some cases detection limits are unusually high. This might be sufficient to shed doubt upon data despite its validation by the national data suppliers.

Pollutant deposits and air quality at coastal stations in 2003

1 The OSPAR CAMP monitoring programme, 2003

Geographical coverage

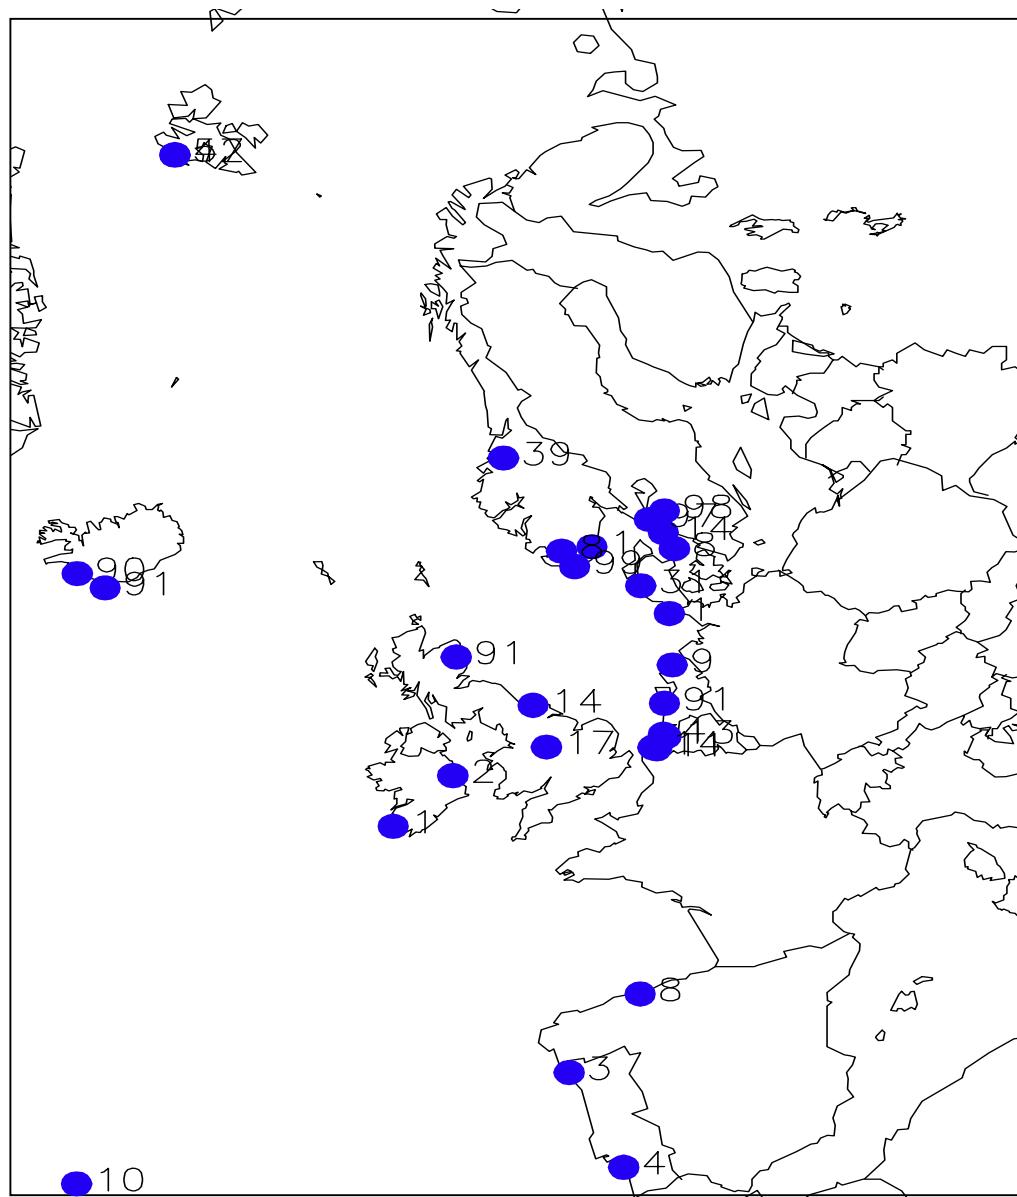

Figure 1.1: Monitoring sites reporting to OSPAR in 2003

Numbers refer to stations listed in table 1.1

The distribution of monitoring sites reporting during 2003 was unchanged in all countries reporting data except for the UK. Most noteworthy is that France did not report 2003 observations. Otherwise, coverage of the southern North Sea, the

Skaggerak and the Kattegat is very good. Observations in northern regions more dispersed.

Reported observations of pollutant wet deposition and of air quality have dissimilar geographical distributions. The following table details the monitoring stations, and indicates their supply of airborne and/or of precipitation pollutant monitoring data. Furthermore, not all stations report all pollutant components, leading to dissimilar coverage of the various pollutants. This can be observed in the mapped deposition presented in chapter 2.

Table 1.1: Stations reporting precipitation and air quality to OSPAR in 2003

Country	Station number	Station name	Latitude	Longitude	Elevation/ Altitude (m)	Distance from sea (km)	precipitation(p) airborne(a) monitoring

1.1.1 Coverage of pollutants

The Mandatory lists of components within the CAMP are not fully observed. Whilst a half of Parties did report all precipitation components, two of twelve countries reported less than half of the mandatory precipitation pollutants. The least reported are the two toxic substances mercury and lindane. For air concentrations, reported observations are generally fewer, with a quarter of Parties not reporting any of the Mandatory list. Ground truth on the state of atmospheric pollution of OSPAR coastal waters was more sparse than for 2002.

1.1.2 Timeliness of reporting

Reporting of data in time for INPUT's consideration was poorer for the 2003 observation year. In tables 1.4 and 1.5 the timetable for reporting as given in the CAMP Principles, and the actual reporting achieved are set out. Nevertheless, more than half of countries achieved reporting within or close to the timetable. The latest submitted data to be included in this report was received on 1st April 2005.

Table 1.4: The timetable for data reporting according to the CAMP Principles

30 th June	Call for metadata and data issued from NILU (regarding new data and metadata), with instructions and reference to supporting software(e.g. where to find tools on the NILU website).
30 th September	Participants submit data and metadata via email or on diskette, in specified formats.
31 ^{s^t} October	NILU returns data and metadata via email or on diskette in the form of a 'validation report' to data originators for verification and signing off by the data originators within two weeks of reception.

2 Observed Pollutant Depositions, 2003

This section gives an overview of atmospheric conditions around the North East Atlantic in 2003, listing and displaying the annual average values of the mandatory list substances.

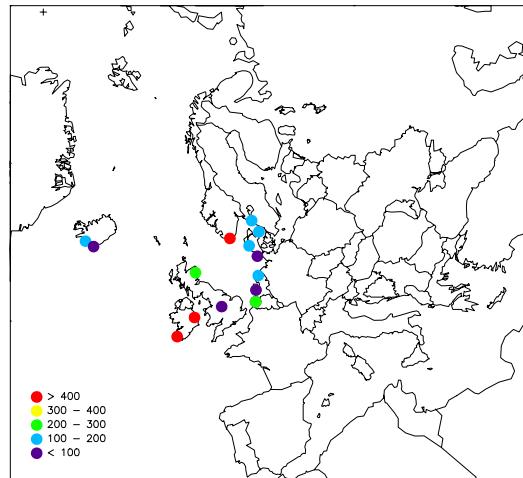

For Mandatory list metals, the observed concentrations and depositions during 2003 are presented in tables 2.1 and 2.2 (mercury). The corresponding deposition distributions are displayed in figures 2.1-2.8. The organic pollutant lindane is given in table 2.3 and figure 2.9. Similarly, for nitrogen the depositions and concentrations in precipitation are tabulated in table 2.4, with the distribution of depositions presented in figures 2.10 and 2.11. In calculating deposition rates the CAMP principles have been followed with respect to interpreting detection limits, i.e. where data was flagged '780' (observation below detection limit, value is best estimate), this data value was employed; where '781' was flagged (observation below detection limit, value is detection limit), a value of half the detection limit was used.

Table 2.1: Reported mean annual precipitation concentrations of mandatory metals ($\mu\text{g/l}$). These are precipitation weighted values, and precipitation amounts are given as mm.

3 Temporal trends, and quality control

3.1 Seasonal patterns

Nitrogen and lindane are selected here for display of temporal trends, metals having been displayed during 2002. An attempt has been made to provide broad geographical information through averaging across stations. The potential impact of the absence of data from France must be recognised in these figures.

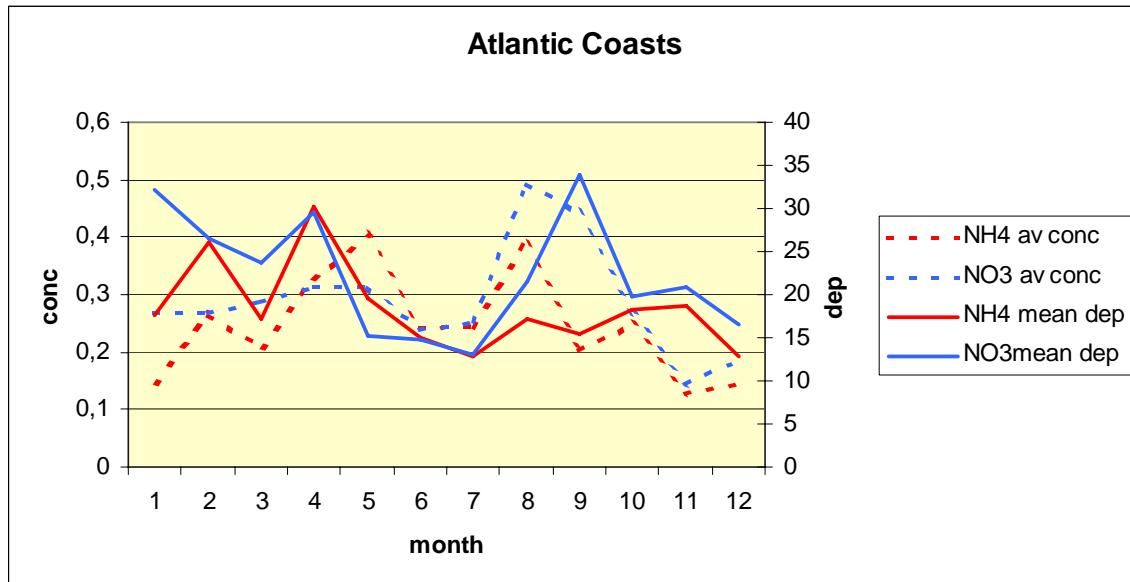

Figure 3.2 Seasonal pattern in nitrogen deposition to the Atlantic coastline during 2003, mg/l and mg/m²/month

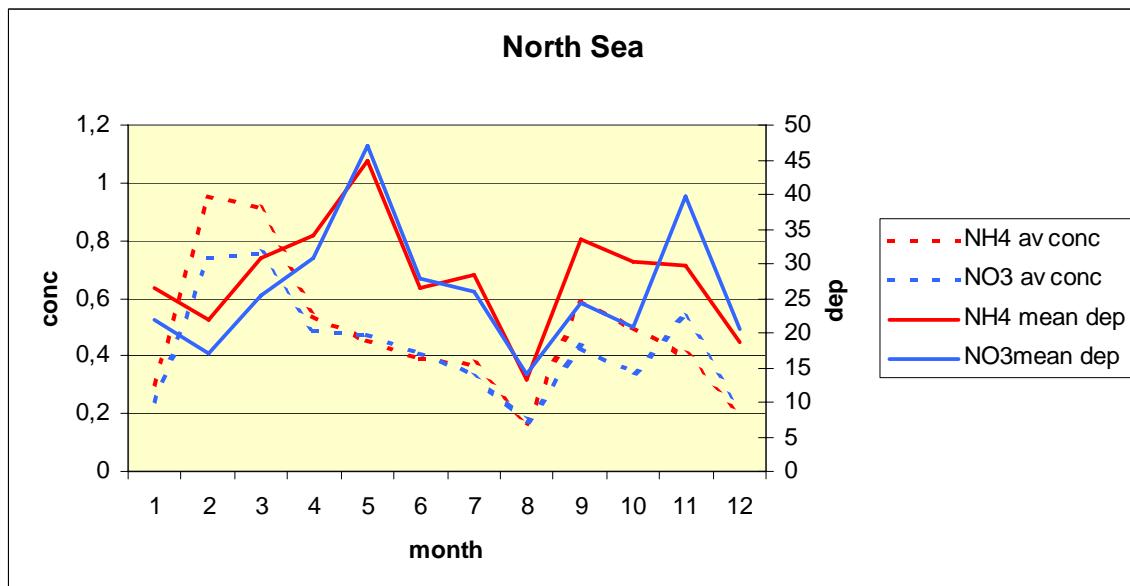

Figure 3.1 Seasonal pattern in nitrogen deposition to the North Sea coastline during 2003, mg/l and mg/m²/month

3.2 Quality Control

Quality control remains a serious issue. This task is undertaken by countries themselves, with NILU restricted to assembling and presenting data. However, there are important concerns. In this section two issues will be indicated:

- a) detection limits: the case of lindane
- b) internal quality control

a) detection limits: the case of lindane

Review of summary data during 2002 indicated elevated depositions of lindane occurring in the southern North Sea. Furthermore, the majority of Parties to INPUT 2005 did not support suggestions from some to remove lindane from the priority list on account of its continued presence. In follow up the reported data for 2003 has examined more closely. This indicates that there is likely a continued elevated deposition of lindane to the southern North Sea, despite the phasing out of lindane some years ago, thus confirming the value of observation. However, the magnitude of lindane deposition may be notably less than the summary data had suggested during previous years. At first review this appears due to uncertain monitoring and poor detection limits in Parties reporting the highest depositions.

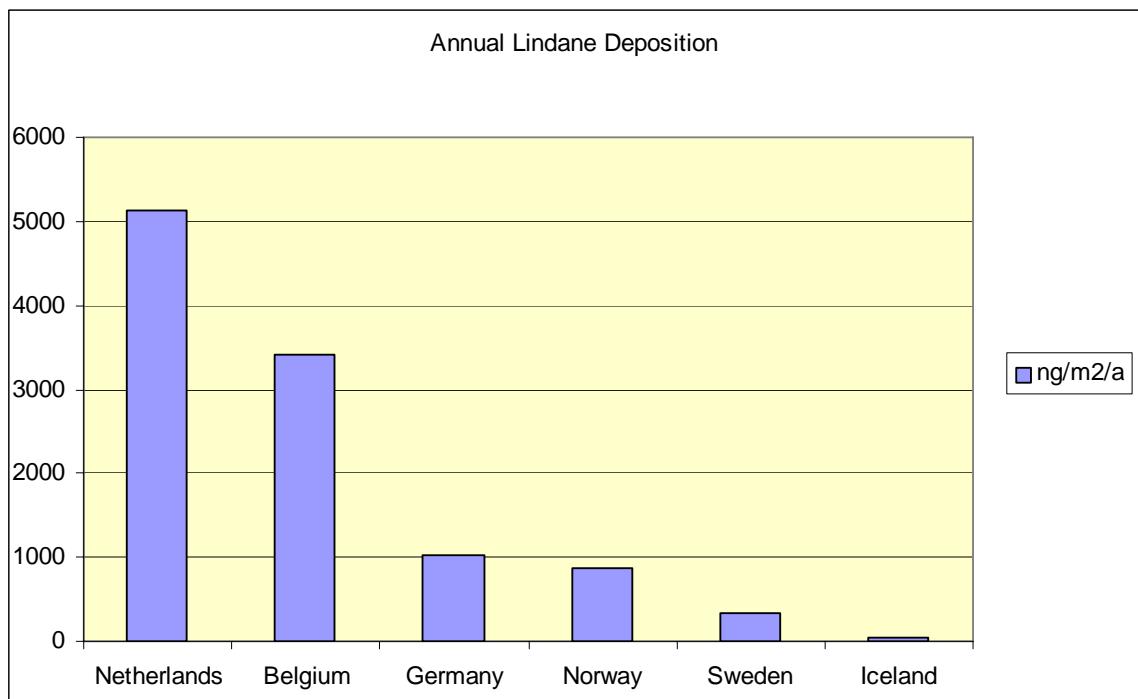

Figure 3.3. Summary annual data for lindane deposition, ng/m²/a, during 2003. Calculated according to CAMP Principles. Further review indicates that the data for Netherlands and Belgium likely overstates reality.

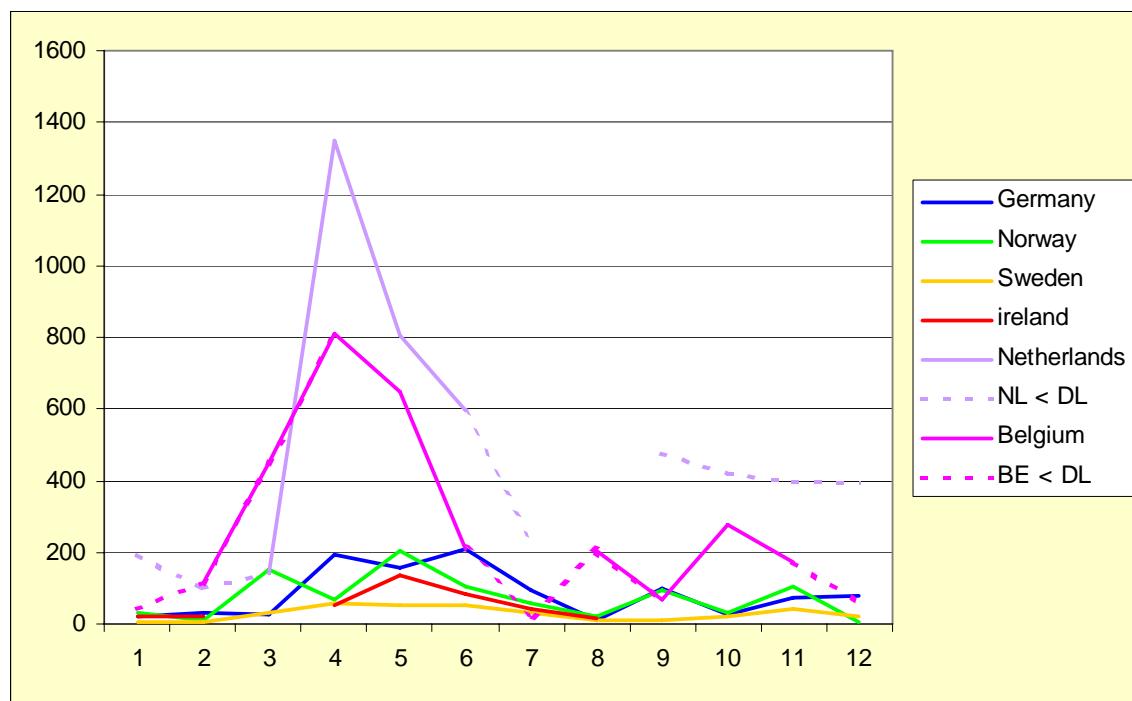

Figure 3.4 Monthly depositions of lindane (ng/m²/month). All values above detection limit except where indicated. Calculated according to CAMP Principles (below detection limit values are 50% of reported detection limit).

Table 3.1: Summary of analysis of low concentrations of lindane. Table shows the lowest concentrations successfully analysed without reaching the detection limit, and the highest reported detection limits. Each monitoring period is reported separately, hence detection limits vary.

Country	Lowest concentration analysed above detection limit	Highest reported detection limit
Belgium	6,000	2,000
Germany	0,150	none below DL
Iceland	0,030	none below DL
Ireland	none above DL	2,700
Netherlands	10,000	10,000
Norway	0,115	none below DL
Sweden	0,11	none below DL

When the monthly reported deposition data is examined, it is found that the countries reporting the greatest depositions are only able to successfully observe high concentrations. During the low input months, these countries typically find concentrations below detection limit. However, cross comparison indicates that other countries are quite able to observe lower concentrations throughout the whole year. The data from these countries displayed on a suitable scale does

indicate higher inputs between the months of March and June. Peak months supplying around 20% of the annual total at these sites, but still at a rate 4-6 times lower than reported from the high reporting stations. It is unclear why detection limits are elevated. Concentrations in the nanogram scale are not particularly low, and the very even step in monthly reported concentrations (above or below detection limit – see Appendix data tables) indicates uncertain data.

b) internal quality control

The discussion concerning high detection limits for lindane is of course equally relevant under the heading of internal quality control. The cross comparison between countries highlights an issue which should already be apparent at data source.

Whilst comparison between countries is a clear benefit of the coordinated CANP programme, this section will provide an example of the benefits of cross-comparison within countries. The CAMP Principles call for side by side observation in order to check the results produced by bulk precipitation sampling. This provides the opportunity for in-country quality control of data prior to submission.

Table 3.2 gives the results from one country of side-by-side wet-only and bulk samplers. These show higher depositions in the wet only samplers than in the wet plus dry bulk samplers, and the patterns between samplers and metals is very inconsistent. The precipitation values alone (not shown) also indicate the likelihood that the sampler is not opening sufficiently quickly.

Such errors can be noted by data originators, thus permitting in-house quality control prior to data submission. In response to the problems encountered with data in table 3.2, the data originator in Belgium lodged a response with the CAMP data manager after INPUT 2005, including the following:

“In 2003 we have performed background measurements with bulk sampling at 6 other sites in Flanders . Data from these locations have shown us that the Knokke site is for some elements probably influenced by non-located local sources. Duplo measurements at this site have also shown in some cases an unexplainable big variability which indicates external influences.

Action: At the end of 2004 the measurements at the Knokke site have been stopped and new sampling equipment has been installed at a new location.....”

Table 3.2: Comparison of wet only and bulk sampler results from one country.

4 Some points

- Reporting by OSPAR countries was poorer during 2003. One country did not deliver any data whatsoever. Only a third of countries completed the Mandatory monitoring programme.
- Reporting occurred largely in adherence to the timetable. However, some deliveries were extremely late, being received on April 1 2005, four months after the draft data report had been delivered to INPUT.
- Review of reported data on lindane indicates a continued deposition some years after the substance was legally phased out and formal emissions ceased, thus underlining the value of observation.
- However, there are issues of data quality to be answered. There is some evidence of rather superficial data quality control on occasions, which undermines the validity of the picture being presented. Very high reported concentrations being indicated as valid by national data originators whilst observations in neighbouring countries are much lower is an example. Consideration of such spatial features across national borders may assist national data originators identify potential weaknesses not evident in national datasets.
- Participation in international intercomparison exercises is strongly encouraged. This has produced benefits during 2003, and can be taken further in future.

Appendix A

Reported monthly observations of Mandatory, Voluntary, and additional components

(major ions used solely for QA not listed)

Belgium

TITLE Pollutant deposits and air quality at coastal stations in 2003		PROJECT LEADER Kevin Barrett	NILU PROJECT NO. O-97146
AUTHOR(S) Kevin Barrett Center for Ecological Economics		CLASSIFICATION * A	
		CONTRACT REF. Alan Simcock, Chairman	
REPORT PREPARED FOR OSPAR Commission New Court, 48, Carey Street, London WC2A 2JQ, United Kingdom			
ABSTRACT This report is the assimilated record of observed input of atmospheric pollutants to the OSPAR seas in 2003, and of the associated concentrations of pollutants in the ambient air of the OSPAR region. Observations have been conducted under the terms of the CAMP, the Comprehensive Atmospheric Monitoring Programme, which calls for Mandatory Monitoring of a range heavy metals, organic compounds and nutrients in precipitation and air, and encourages participation in a Voluntary Monitoring of additional compounds.
